Variance of L-HH from 1.5 years ScanSAR time series

- ✓ Dependence of L-band NRCS change on harvesting and plating cycles for better classification
- ✓ Knowledge about NRCS signal change in relation to deforestation

Panting & Harvesting progress map as of March 31, 2009 provided by APRIL

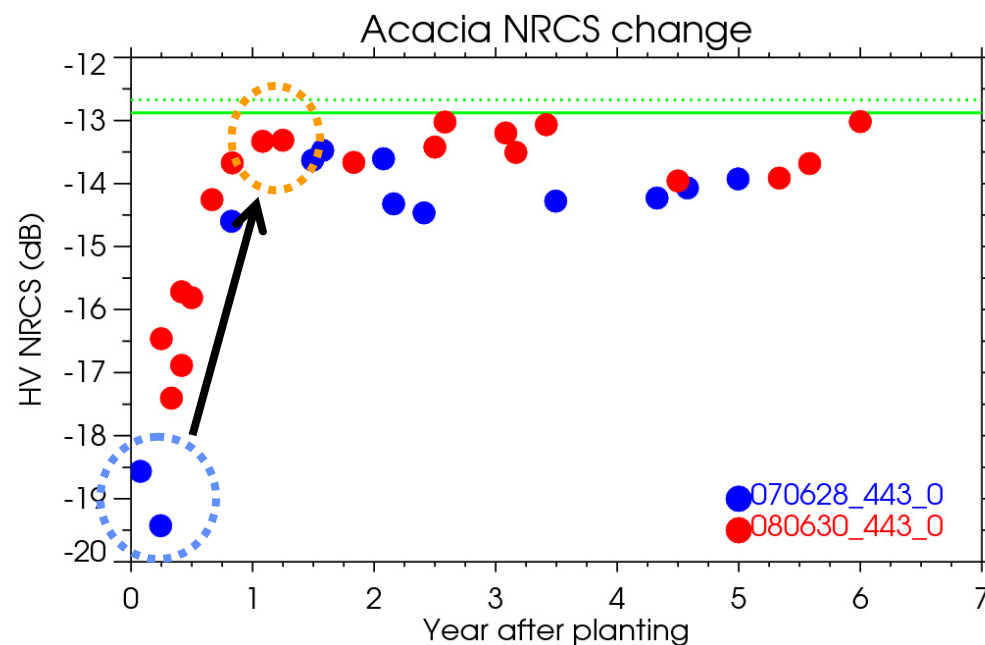

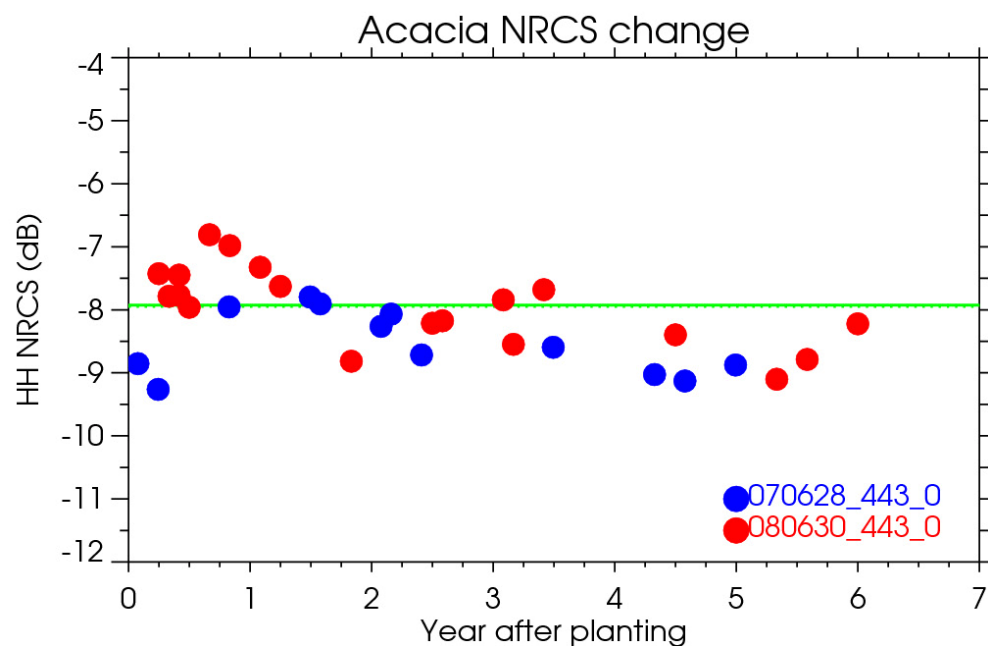

- ✓ HH & HV signal change as a function of time after plantations (tree age) by using FBD images.
- ✓ HH signal change in relationship to a planting & harvesting cycle by using ScanSAR data.

HH & HV signal of acacia plantation as a function of tree age

- based on 2007/6/28 and 2008/6/30 FBD 343 data and planting time

- ✓ HH seems to decrease gradually .
- ✓ HV rapidly increases and gets saturated after almost 1 year.

POL 23.1 2009/5/13

HH: little large
HV: almost same

Growth is fast!!

Photos taken 2009/4/6

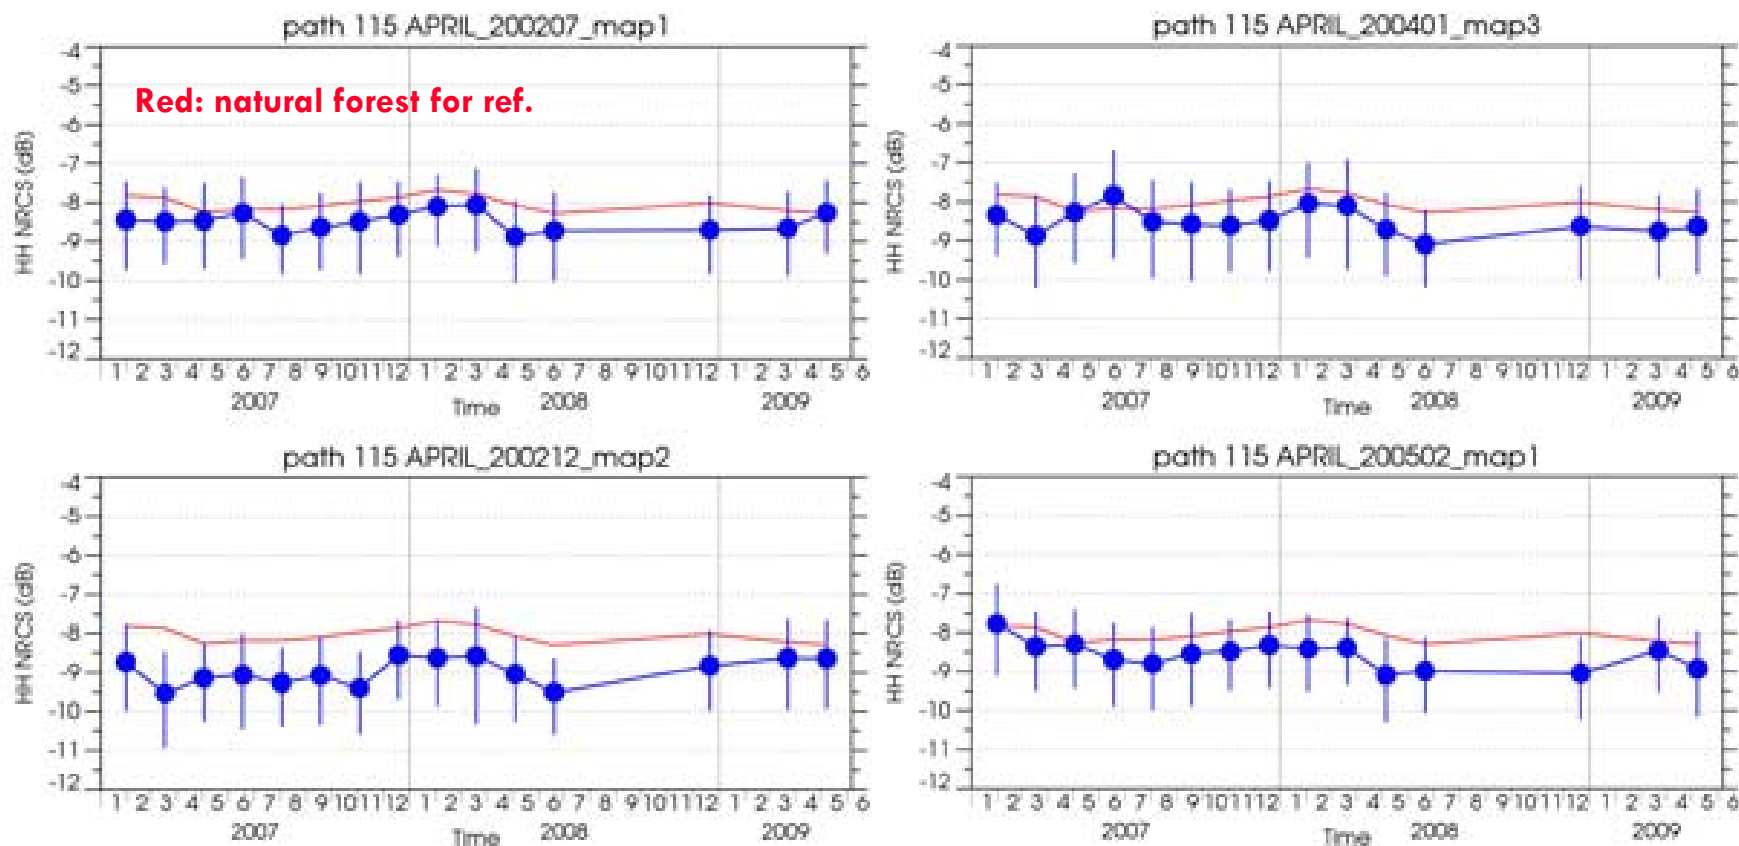

Planted in Mar 2008 (about 1.1 year-old)

Planted in Jul 2005 (about 3.8 year-old)

L-HH time series of acacias planted in **2002-2005** (older acacias)
-derived from ScanSAR (path 115: inc. angle~36°)

- ✓ Same seasonal cycle and amplitude as natural forests.
- ✓ Signal level: 0.5-1 dB smaller than natural forests.

ScanSAR-derived L-HH time series of acacias planted in **2007-2008**
(including harvesting and planting)

Planting

- ✓ Extremely large signal just before planting: probably due to harvesting
- ✓ **Large amplitude: lower in dry season and higher in next rainy season (within 1 year-old)**

ScanSAR-derived L-HH time series on acacia planted in **2009**

- cases of recent harvesting and planting

path 115: inc. angle $\sim 36^\circ$

Harvesting

Planting

path 118: inc. angle $\sim 24^\circ$

- ✓ Stronger HH signal on baby acacia has strong **inc. angle dependency**.
- ✓ Their differences (2-3dB) can be explained by **a theoretical backscattering from bare soil**.

Similarity to acacia plantation signal

ALOS

Results

-HH changes on plantation cycle

K&C Initiative

An international science collaboration led by JAXA

- ✓ Similar HH characteristic is expected for deforested areas.
- ✓ For deforestation monitoring by ScanSAR (HH), incidence angle dependency should be taken into consideration.

Summary

- ✓ **Tree-age-dependent HH & HV signal on acacia plantations**
 - ✓ HV increases rapidly and is saturated after 1 year.
 - ✓ HH gradually decreases getting 0.5-1 dB lower than those of natural forests after 2 years.
 - ✓ Higher HH signal especially during first year seems to be attributed to **stronger surface scattering components** (explained by roughness, moisture contents and arrangement ?).

- ✓ **HH signal change associated with a harvesting and planting cycle**
 - ✓ HH of elderly acacias (3-6 years old), which are 0.5-1 dB lower than that of natural forests, shows a similar seasonal cycle and amplitude to that of natural forests.
 - ✓ HH of younger (0-2 years old) acacias has larger variability, being higher than that of natural forests in rainy season.
 - ✓ High HH characteristic over young acacias has incidence angle dependency, which can be explained by a theoretical surface scattering model (roughness, moisture contents and arrangement).
 - ✓ For deforestation monitoring by ScanSAR (HH), this incidence angle dependency should be taken into consideration.

Natural forest

Co-pol

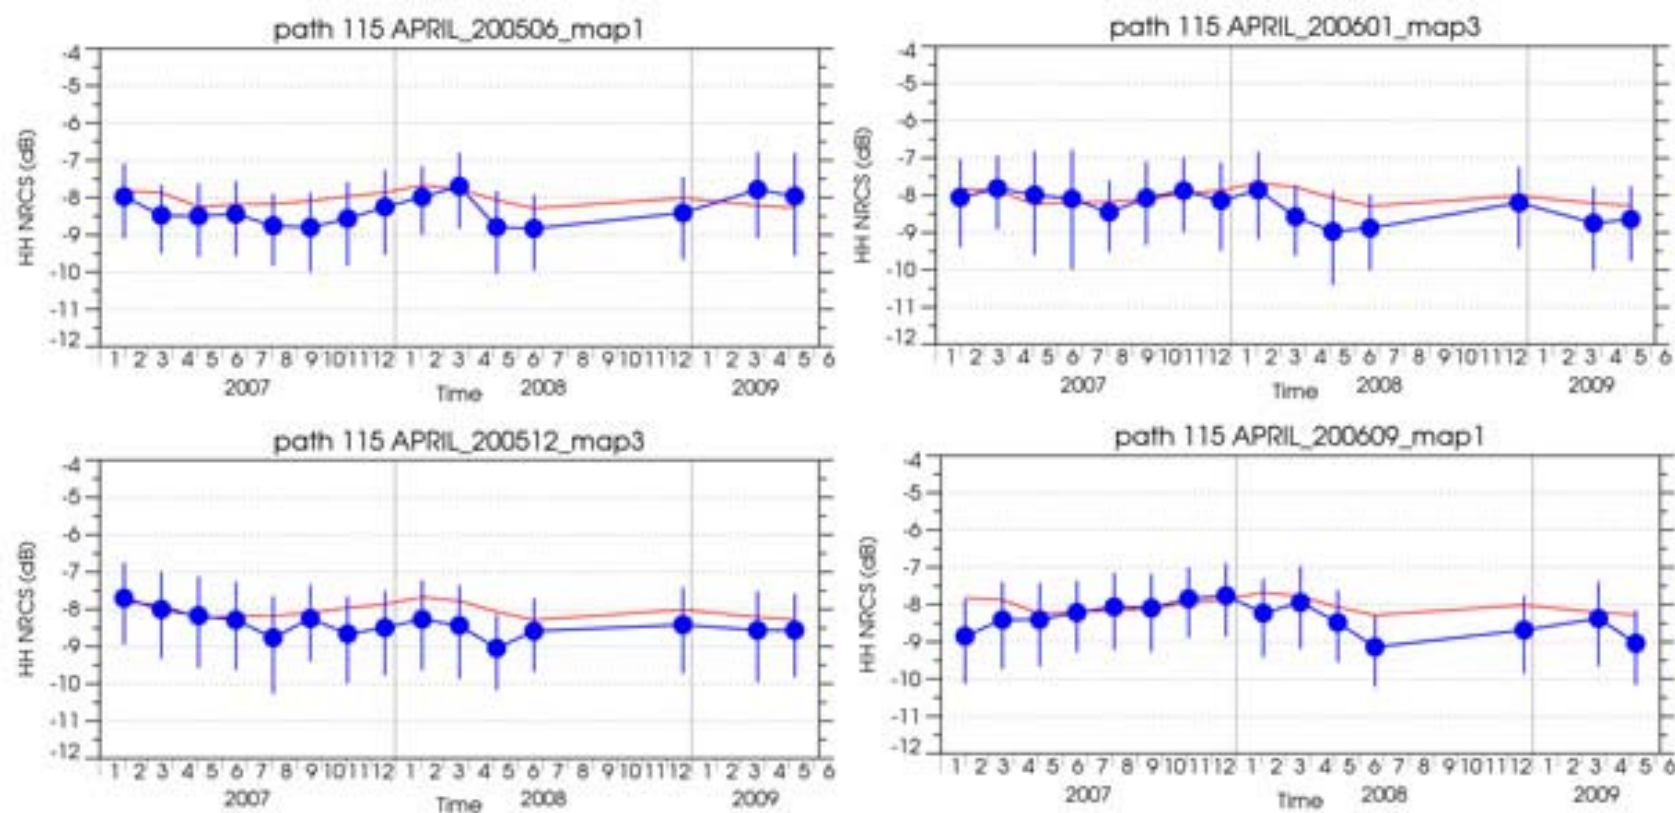

X-pol

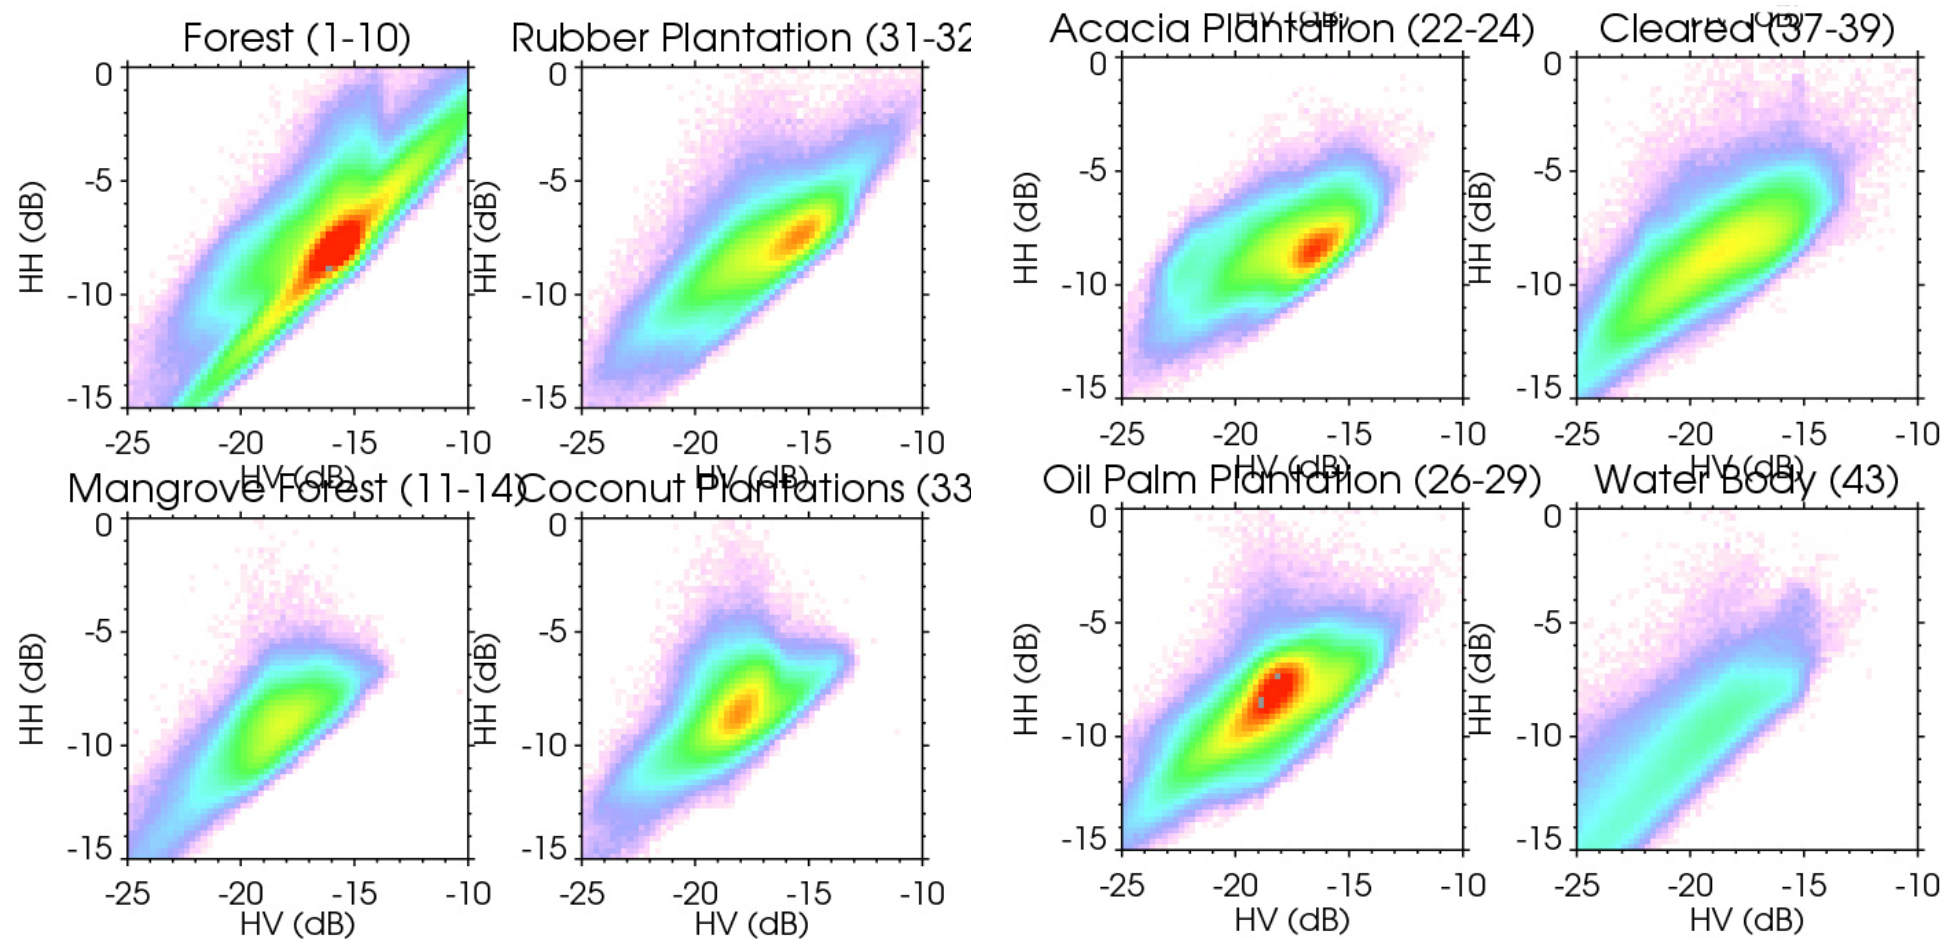

ScanSAR-derived L-HH time series of acacias planted in **2005-2006** (1-3 year-old acacias)

- ✓ Same seasonal cycle and its amplitude as natural forest.
- ✓ **Signal level: almost same as natural forest.**

2-D histograms as functions of HH & HV NRCs for main land types

- ✓ **HH&HV: Natural forest \approx acacia and rubber plantations**
 - ✓ Classification by single intensity mosaic is difficult.
- ✓ **HV: Natural forest 2~3dB larger than other plantations and cleared areas**
 - ✓ Detection new deforested area

ALOS

Results

-HH changes on plantation cycle
