DESCRIPTION

This algorithm provides a merger of all available SSM/I and TMI microwave precipitation estimates into a "high-quality" (HQ) precipitation estimate. The SSM/I estimates are computed with the GPROF 6.0-SSMI algorithm in NASA/GSFC Code 912 and the TMI estimates are computed with the GPROF 5.0-TMI algorithm (the real-time TRMM 2A12 product). Before merger the SSM/I are calibrated to the TMI using separate global land and ocean histograms based on coincident time-space matched data.

SPECTRAL INTERVALS AND APPLICABLE SATELLITES

The input to HQ (3B40RT) consists of pre-computed precipitation estimates based on single-satellite passive-microwave data. At present we employ the GPROF to create the input estimates, and in common with other physically-based algorithms, GPROF uses all available bands from modern conic-scan passive microwave imagers:

- 7 channels on DMSP F-13,F-14,F-15 Special Sensor Microwave/Imager (SSM/I)
- 9 channels on TRMM Microwave Imager (TMI).

The approach is equally applicable to other "high-quality" precipitation estimates, e.g. from Advanced Microwave Scanning Radiometer (AMSR), TRMM Precipitation Radar or Advanced Microwave Sounding Unit-B (AMSU-B) data. For each such new set of input precipitation estimates, the key step is to develop a calibration between the reference set of precipitation estimates (currently TMI-based) and the new set. Taking TMI precipitation as the standard for the sake of illustration, preliminary work indicates that the histograms of PR and AMSU-B rain rate estimates at the 0.25x0.25-deg scale require more aggressive calibrations than are currently applied to SSM/I estimates.

Land/ocean surface type data

ADDITIONAL COMMENTS

Introduction

The HQ is the first stage of a system to produce the "TRMM and Other Data" estimates in real time. The system was developed to apply new concepts in merging quasi-global precipitation estimates and to take advantage of the increasing availability of input data sets in near real time. The overall system is referred to as the real-time Multi-Satellite Precipitation Analysis (MPA-RT). The MPA-RT is run quasi-operationally on a best-effort basis at the TRMM Science Data and Information System (TSDIS), with on-going scientific development by the research team led by Dr. Robert Adler in the GSFC Laboratory for Atmospheres. Estimates are posted to the web about 6 hours after observation time, although processing issues may delay or prevent this schedule. Due to the experimental nature of these estimates, users are encouraged to report their experiences with the data, and they should expect episodic upgrades or outages as the system develops.

File Contents

Each file starts with a header that is one 2-byte-integer row in length, or 2880 bytes. The header is ASCII in a "PARAMETER=VALUE" format that makes the file self-documenting (e.g., "algorithm_id=3B40RT").

Thereafter five data fields follow. All the fields are on a 0.25-deg lat./long. grid that increments most rapidly to the east (from the Prime Meridian) and then to the south (from the northern edge). Grid box edges are on multiples of 0.25 deg. The data fields are written as binary data in big-endian byte order. The data fields are:

Precipitation(2-byte integer)precipitation_error(2-byte integer)total_pixels(1-byte integer)ambiguous_pixels(1-byte integer; highly uncertain values)rain_pixels(1-byte integer)

All fields are 1440x720 gridboxes (0-360 deg. E, 90 deg. N-S). The first grid box center is at (0.125 deg. E, 89.875 deg. N). Files are produced every 3 hours on synoptic observation hours (00 UTC, 03 UTC, ..., 21 UTC) as an accumulation of all HQ swath data observed within +/-90 minutes of the nominal file time. Estimates are only computed for the band 70 deg. N-S.

Note that we use the term "gridbox" to denote the values on Level 3 data (i.e., gridded data), while we use the term "pixel" to denote individual values of Level 2 data (i.e., instrument footprints). Thus, there can be many pixels contributing to a gridbox.

Both precipitation and random error are scaled by 100 before conversion to 2-byte integer. Thus, units are 0.01 mm/h. To recover the original floating-point values in mm/h, divide by 100. Missings are given the 2-byte-integer missing value, -31999. The remaining fields are in numbers of pixels.

Currently the random error fields are all set to the 2-byte-integer missing value, -31999. This placeholder will be replaced with actual estimates as development proceeds.

The variable ambiguous_pixels is the count of pixels for which the algorithm cannot determine whether the scene has valid or invalid data. It is a subset of the total_pixels and many, but not all, are included in raining_pixels. In general, a "high" fraction of ambiguous_pixels indicates that the grid box value is invalid.

The originating machine on which the data files are written is a Silicon Graphics, Inc. Unix workstation, which uses the "big-endian" IEEE 754-1985 representation of 4-byte floating-point unformatted binary numbers. Some CPUs, including PCs and DEC machines, might require a change of representation (i.e., byte swapping) before using the data. In some cases, the gunzip routine, used to uncompress the data, will change representations automatically.

Dataset Validation

These datasets represent a new initiative and should be considered experimental. Formal validation studies are underway, but are not yet available. The primary limitations on the HQ (3B40RT) are the sparse sampling by the collection of passive-microwave satellites and algorithm drop-outs in regions with icy or frozen surface. We encourage early users to report successes and problems in applying these datasets to their particular applications.

Dataset Status

Beta testing began in early December 2001. An official (experimental) version was instituted in late January 2002.Processing changes occurred on 6 February and 12 March 2002. The ambiguous screening was upgraded for the HQ (3B40RT) as of 09Z 28 February 2003 and for the VAR (3B41RT) as of 00Z 2 March 2003. The GPROF estimates for SSM/I over land and coast were upgraded on 12 February 2004. Fractional coverage by precipitation, volume rain, and ambiguous screening upgrades were made to the calibration of other microwave estimates to the TMI starting 00Z 6 April 2004, and cold land and high rainrate improvements were made to the IR calibration beginning 04Z 15 April 2004.

Users should anticipate a series of versions as the algorithm is developed further. We definitely plan to transition to the new TRMM versions of input (which governs calibration of the SSM/I and IR) when they become available in early 2005. As well, an improved non-real-time MPA is being instituted in the official Version 6 TRMM operational product 3B42.

Example Programs

The data fields are all written with C-language code as blocks of bytes, so there are no extraneous bytes in the files. Because the first two fields are 2-byte integers and the rest are 1-byte integers in each file (to save space), users must exercise care in using FORTRAN direct access to read the data. The FORTRAN example programs read all fields with a single OPEN. Alternatively, the files can be opened with different logical record sizes depending on whether one is reading 2-byte-integer or 1-byte-integer fields. Note as well

that the units of the logical record size is not part of the FORTRAN 77 standard. On SGI machines it is in 4-byte words, but some other systems expect it in bytes. Also, to repeat an earlier comment, the originating machine on which the data files are written is a Silicon Graphics, Inc. Unix workstation. It uses the "big-endian" IEEE 754-1985 representation of 4-byte floating-point unformatted binary numbers, and some CPUs, such as PCs and DEC machines, might require a change of representation (i.e., byte swapping) before using the data.

The FTP site <u>ftp://aeolus.nascom.nasa.gov/pub/merged/software</u> provides several example programs:

read3B4XRT.c	C example
read_header.f	FORTRAN header-read example
read_rt_file.f	FORTRAN single-read example
read_rt_file.pro	IDL example
read_rt_lines.f	FORTRAN line-by-line example
